## Feasibility study about Sullivan Process on the u-channel

*Monday, 25 November 2024 14:30 (30 minutes)*

This work presents a systematic feasibility study on measuring backward deeply virtual Compton scattering (bDVCS) on the pion through Sullivan processes, within the framework of collinear QCD factorization. In this approach, pion-to-photon transition distribution amplitudes (TDAs) are used to describe the photonic structure of the pion. Using the TDA framework considering overlap of light-front wave functions, we aim to estimate the cross-section for DVCS processes and evaluate the prospects for future measurements at electron colliders in the U.S. and China.
